3. (a)
$$E(Y) = E(2.4X-5) = 2.4 E(X) - 5 = (2.4)(19) - 5 = 40.6$$

(b)
$$Var(Y) = Var(2.4 \times -5) = Var(2.4 \times) = (2.4)^2 Var(X)$$

= $(2.4)^2 (5.3) = 30.528$

$$V = \frac{\sqrt{3}}{2}hb^{2} \implies V(b+\Delta b, b+\Delta h) \approx V(b, h) + \frac{\partial V}{\partial b}(b, h) \Delta b + \frac{\partial V}{\partial h}(b, h) \Delta h$$

$$u_{V} = \sqrt{\frac{3}{4} b^{4} u_{h}^{2} + 3 h^{2} b^{2} u_{h}^{2}}$$

At
$$(6, h) = (4.8, 8.5)$$
, $V = \frac{\sqrt{3}}{2}(4.8)^2(8.5) = 169.6024$

and
$$u_v = \sqrt{\frac{3}{4}(4.8)^4(0.4)^2 + 3(8.5)^2(4.8)^2(0.3)^2} = 22.65$$

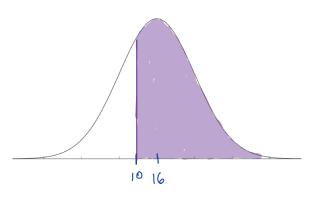

$$\Rightarrow$$
 $\sqrt{=170 \pm 20 \text{ cm}^3}$

5. (a) A 94% CI for
$$\mu$$
 is constructed from $\overline{X} \pm gt(0.97, Jf = 11) \cdot \frac{S}{Jh}$.

That is,
$$21.6 \pm (2.096) \frac{5.14}{\sqrt{12}} \Rightarrow (18.49, 24.71).$$

$$E(Y-X) = E(Y) - E(Y) = 53 - 37 = 16$$

$$Var(Y-X) = Var(Y) + Var(X)$$
 (by independence)
= $25^2 + 7^2 = 674$

How code for Problem 1 solutions might look

manySums <- do(5000) * sum(~rbeta(50, alpha2, beta1))

myVar = alpha2*beta1/((alpha2+beta1)^2*(alpha2+beta1+1))

mu = alpha2 / (alpha2 + beta1)

```
c(alpha1, lambda1, lambda2, alpha2, beta1)
## [1] 2.2800000 7.1600000 0.1061571 7.5100000 6.3400000
f = makeFun(dgamma(x, alpha1, lambda1) ~ x)
xF = antiD(x * f(x) ~ x)
xxF = antiD(x^2 * f(x) ~ x)
The expected value:
eX = xF(Inf) - xF(-Inf); eX
## [1] 0.3184358
The variance:
eXsq = xxF(Inf) - xxF(-Inf); eXsq
## [1] 0.1458756
aVar = eXsq - eX^2
                               mean
                                          E(X^2)
                                                     variance
                               0.3184358
                                          0.1458756
                                                     0.0444743
 (b)
qexp(.7, lambda2)
## [1] 11.34142
```

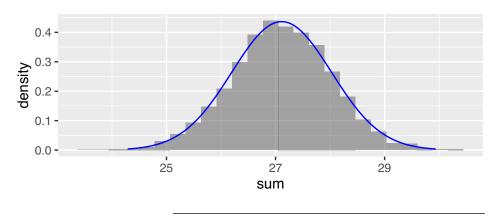

The population from which we are drawing an iid random sample of size 50 is Beta(7.51, 6.34) As per Table 4.5, the mean and variance of this population are

```
\mu = 0.5422383 and \sigma = 0.129286.
```

Thus, the sum of an iid random sample of size 50, by the central limit theorem, as an approximate normal distribution,

```
S \sim \text{Norm}(27.1119134, 0.9141903)
```

```
gf_dhistogram(~sum, data=manySums) |>
   gf_dist("norm", params=c(50*mu, sqrt(50*myVar)), color="blue")
```

(d)

fitdistr(manySums\$sum, "normal")

```
## mean sd
