A

1. (a) $np = (16)(0.8) = 12.8 > 5$, but $n(1-p) = 16(0.2) = 3.2 < 5$.
It is not OK to assume normality.

(b) $SE_{\hat{p}} = \sqrt{\frac{p(1-p)}{n}}$

(c) $SE_{\hat{p}} = \sqrt{\frac{(0.8)(0.2)}{16}} = 0.1$

2. (a) Cases are work weeks

(b) The number of lost work hours

(c) μ = mean # of work hours per week lost to absenteeism.

3. Option (iii)

4. You cannot be certain of the result being significant at the 1% level. For instance, a p-value of 0,3 is significant at the 5% level, but not at the 1% level.
